1 Introduction

1.1 Background and Motivation

In Australia, road accidents are an important public health issue. While road crash fatalities consider attention, many people survive accidents but suffer injuries that require hospital admission. Injuries can create problems for people and cause extra demands on medical services.

Our project uses national hospitalised injury data published by the Bureau of Infrastructure and Transport Research Economics (BITRE). The dataset covers the years 2011 to 2021 and allows us to investigate how hospitalised injuries from road crashes changed over time.

Our target audience includes the general public, students, road safety researchers and policymakers. We aim to present the data in a clear and interactive website so users can understand the overall trends without needing to analyse a large spreadsheet.

1.2 Visualisation Purpose

The purpose of our visualisation is to communicate important patterns and changes in hospitalised road crash injuries in Australia from 2011 to 2021.

Our main questions are:

1. How did the number of hospitalisations change between 2011 and 2021?
2. Which years had the highest and lowest numbers of hospitalisations?
3. How did hospitalisations differ between male and female road users?
4. Which age groups had the highest numbers of hospitalisations?

The website will use interactive charts, tooltips and annotations to help users explore these questions. The expected benefit is to make national injury trends easier to understand and provide evidence that can support public discussion about road safety.
